at the MIT Media Lab  
**2023**

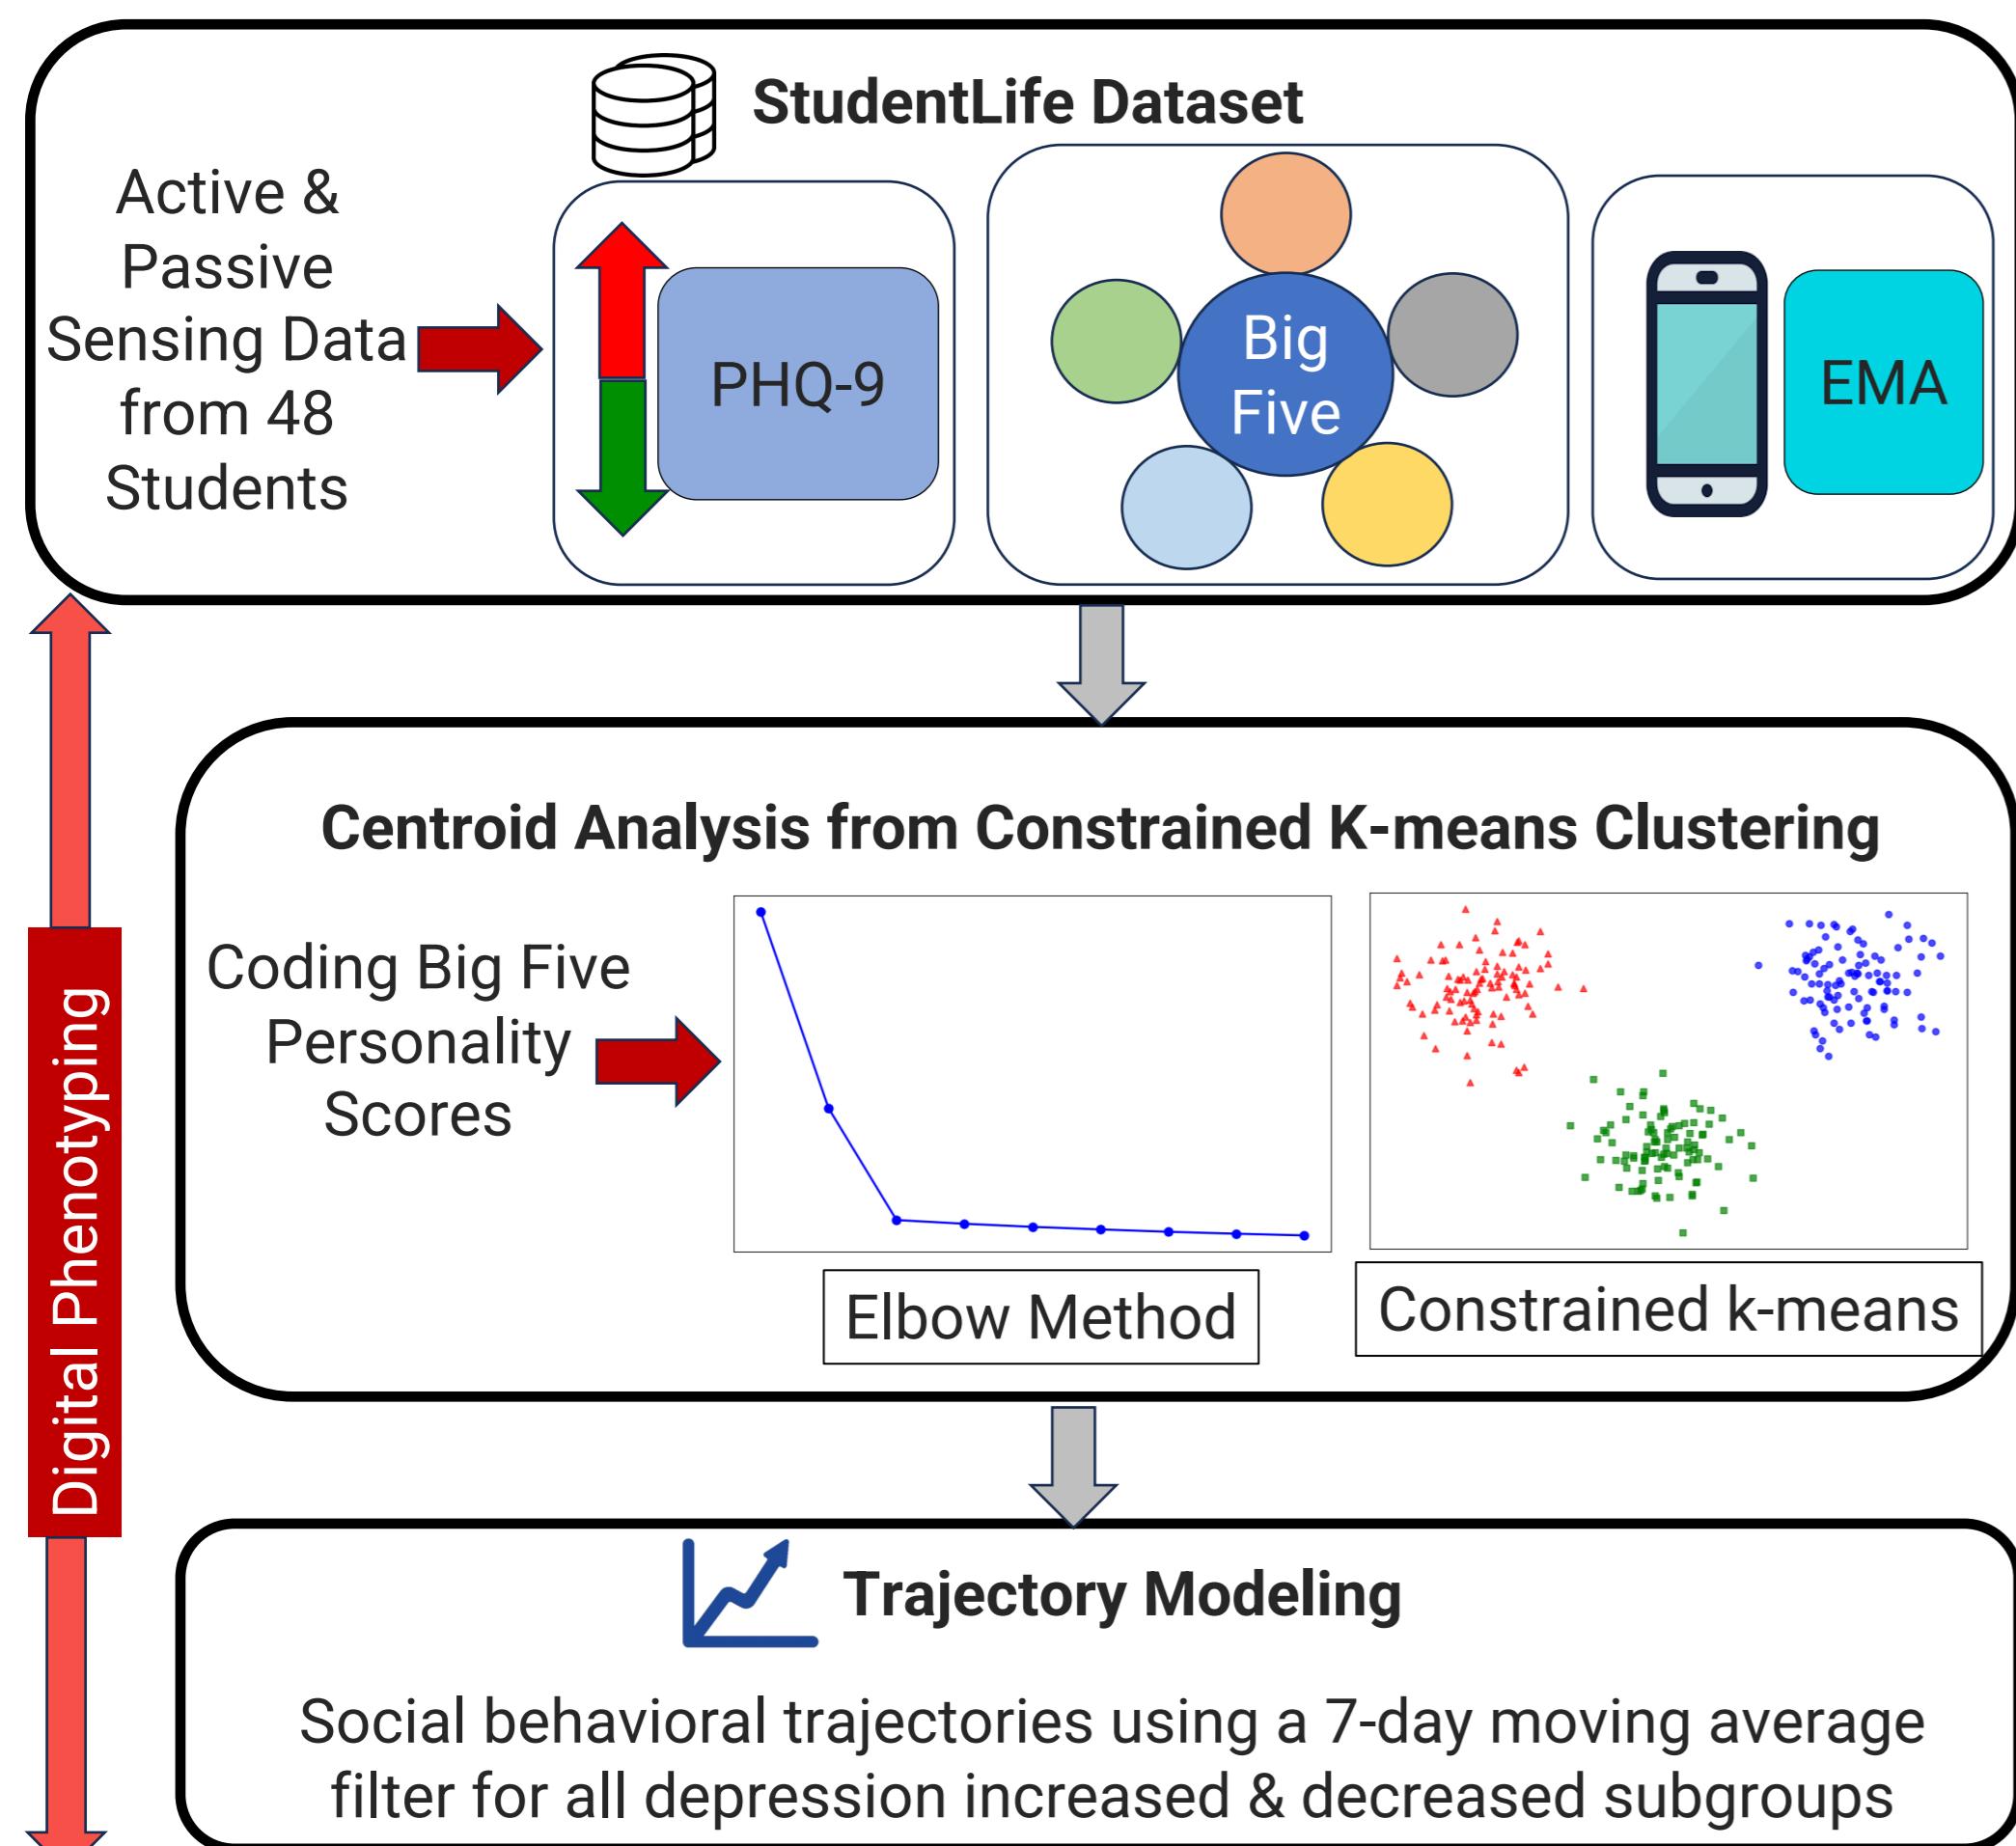

## Motivation

33% of college students experience different mental health disorders, mostly depression

## Objective

Investigating the relationship between depression, personality traits, and social interaction patterns among students

## Methods

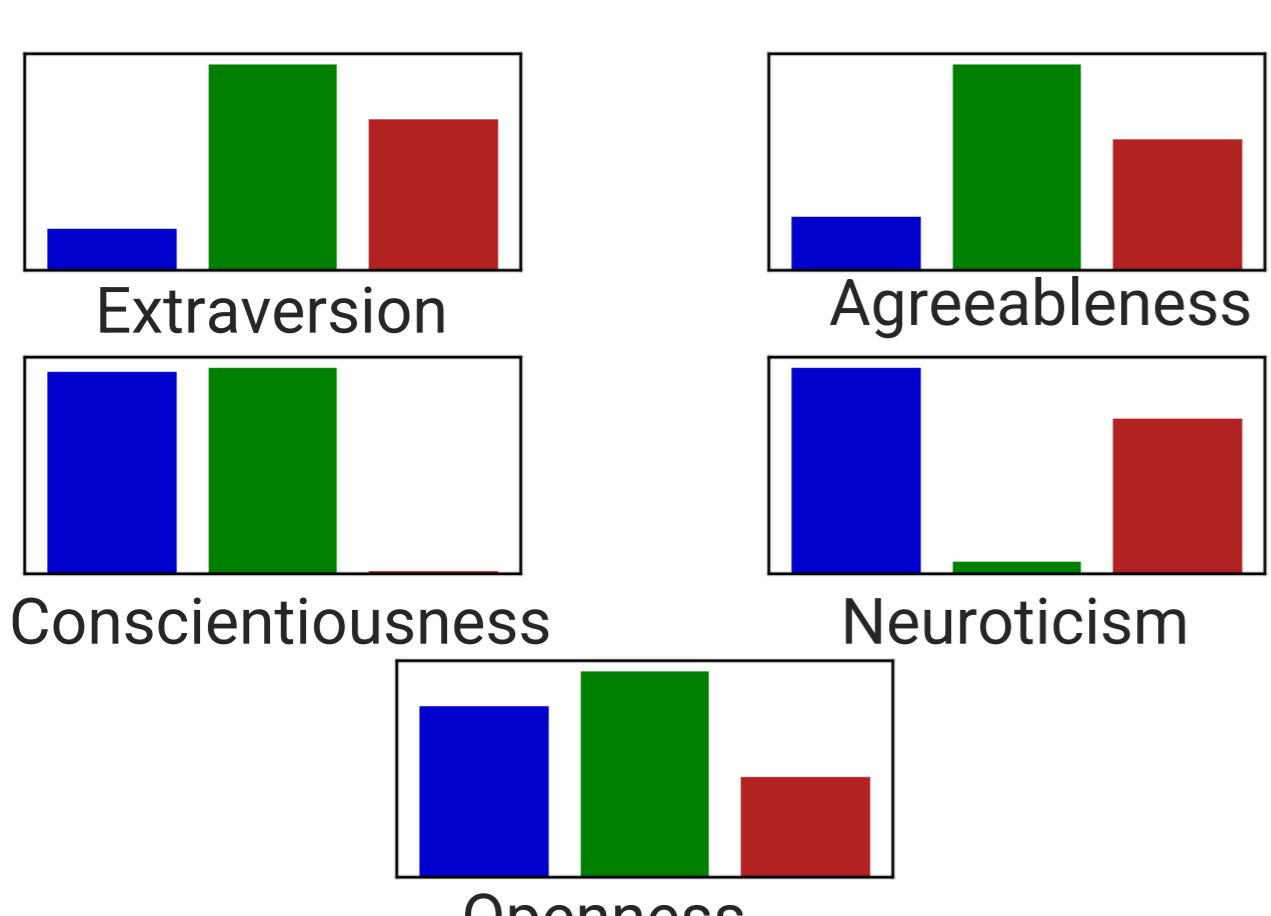

## Results

Clustering analysis identifies three distinct personality traits from elbow point 3. Bar plots show between-person means of each clustering variable, big-five scores separately by cluster:

Cluster 1 ■ 16 students - **high neuroticism**

Cluster 2 ■ 13 students - **high conscientiousness & low neuroticism**

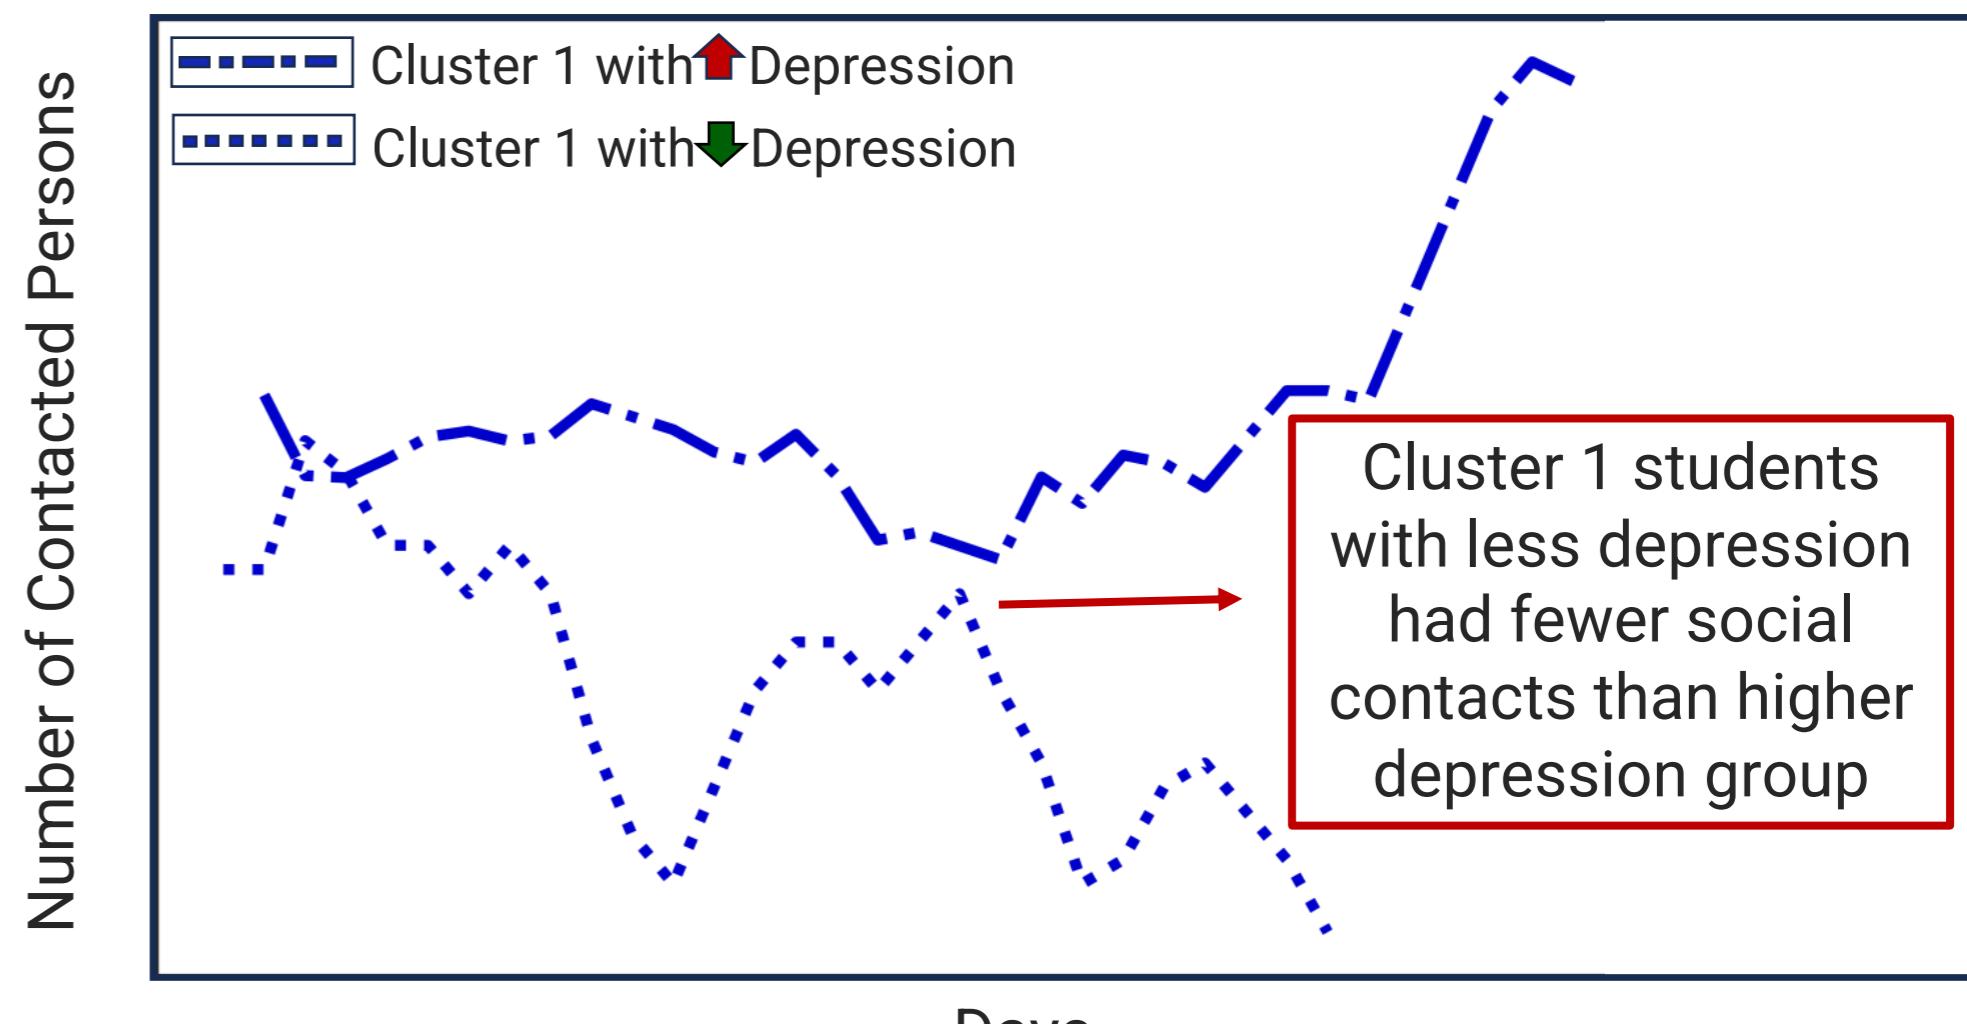

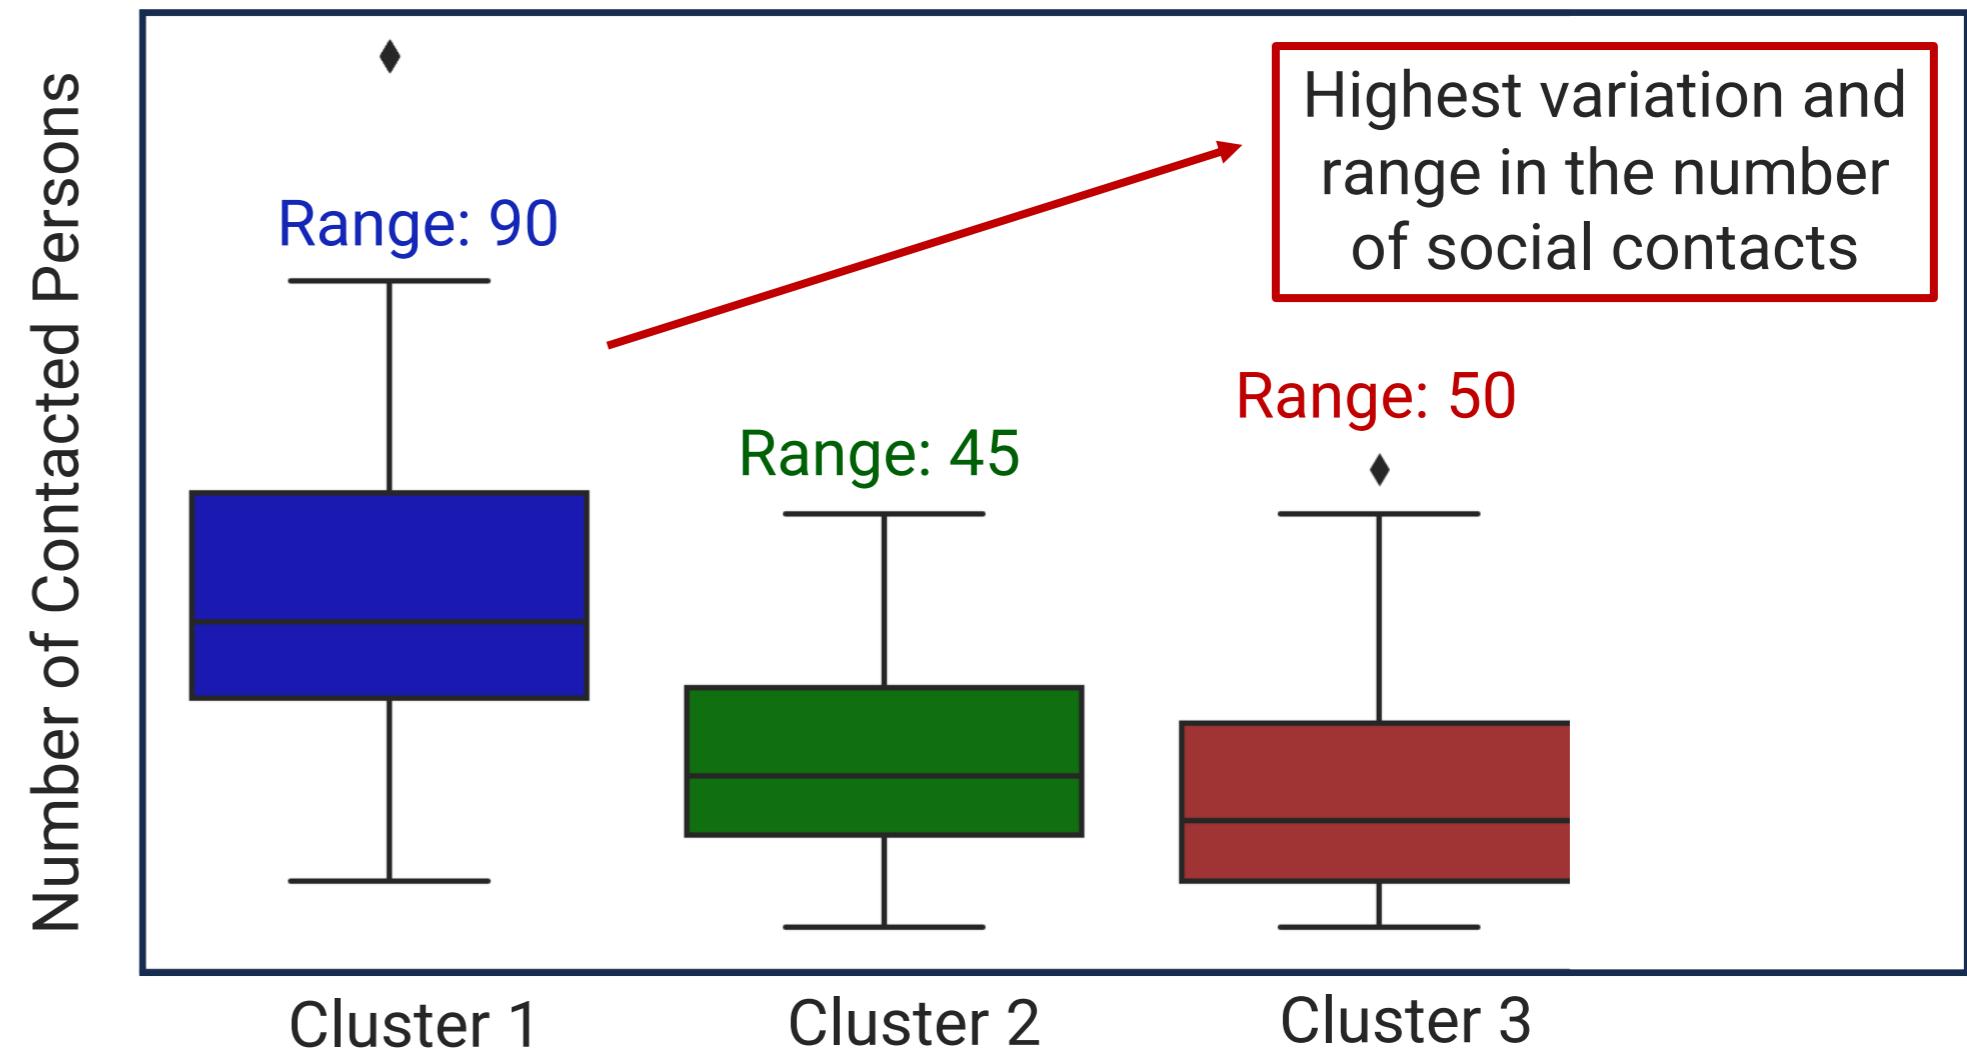

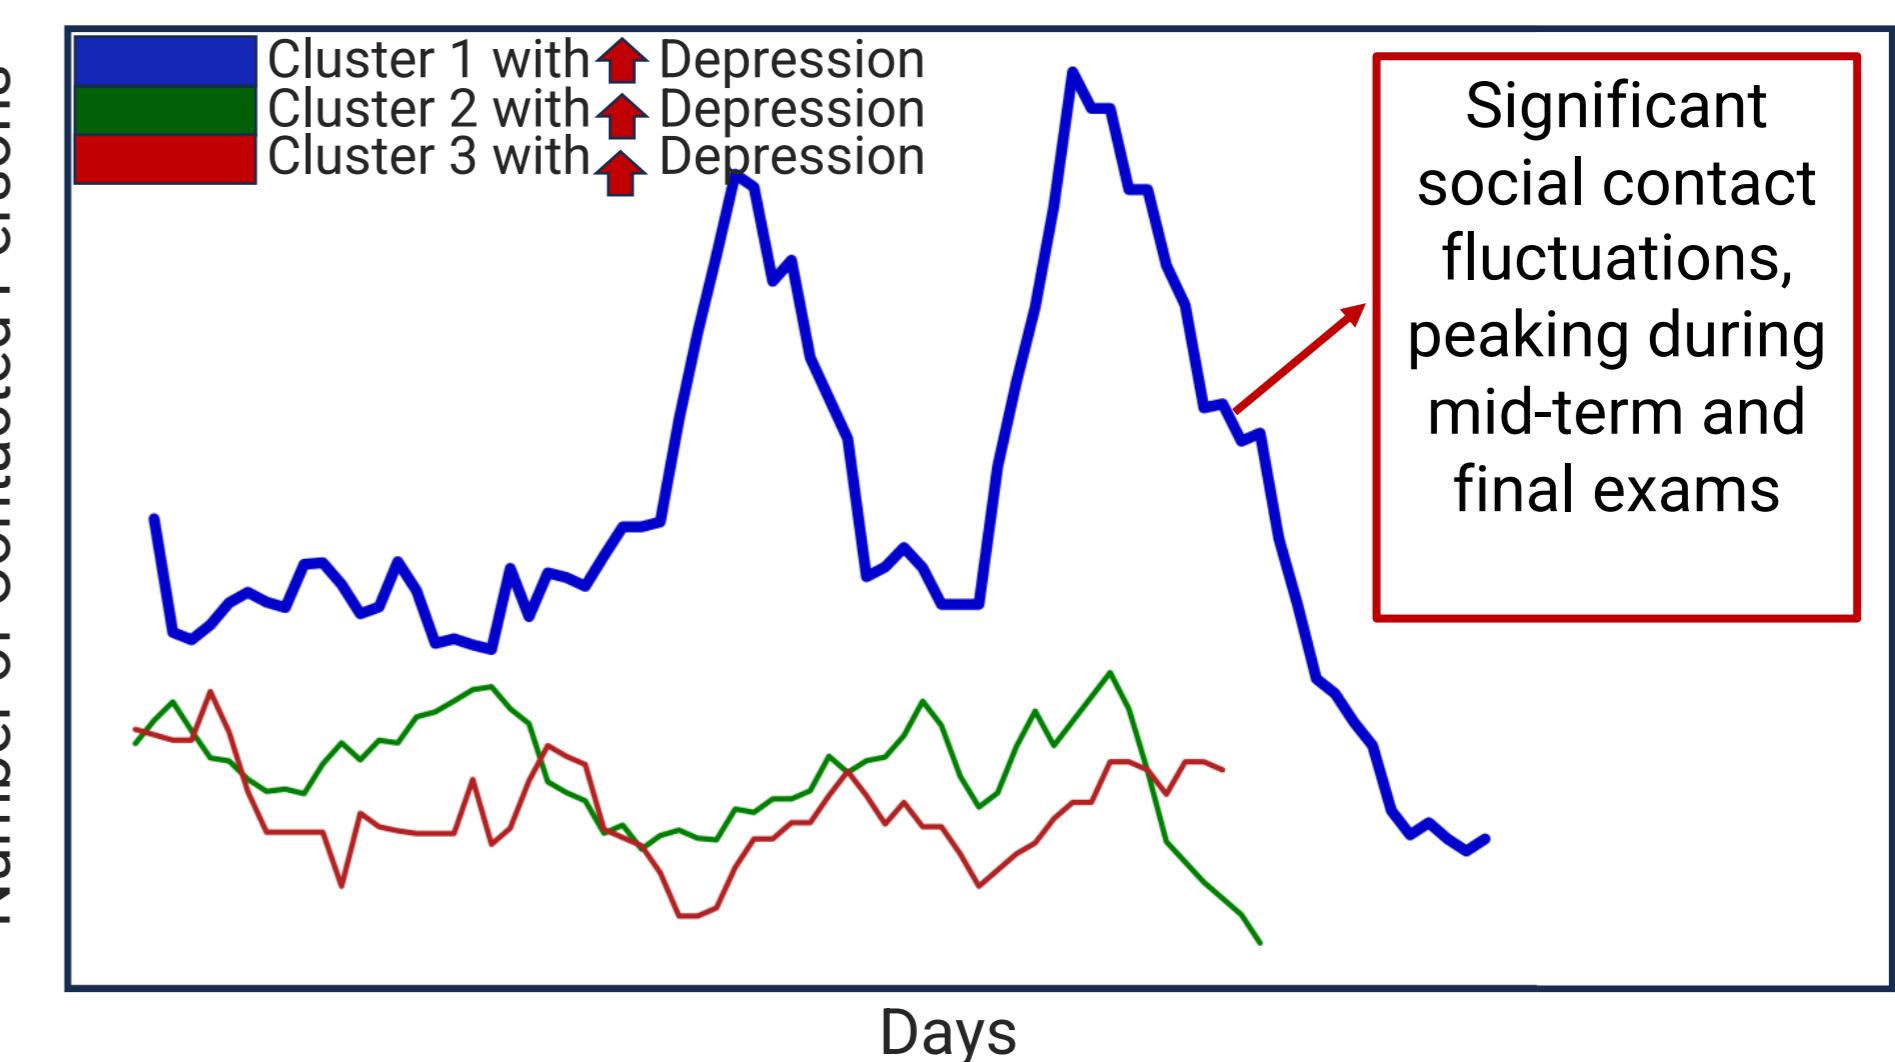

Cluster 3 ■ 17 students - **low conscientiousness**

Survey Type	Variance in PHQ-9 Scores
pre-survey	17.0625
post-survey	<b>27.9743</b>
Cluster 2	
Survey Type	Variance in PHQ-9 Scores
pre-survey	43.2424
post-survey	<b>61.4285</b>
Cluster 3	
Survey Type	Variance in PHQ-9 Scores
pre-survey	7.1838
post-survey	<b>9.3166</b>

## Key Takeaways

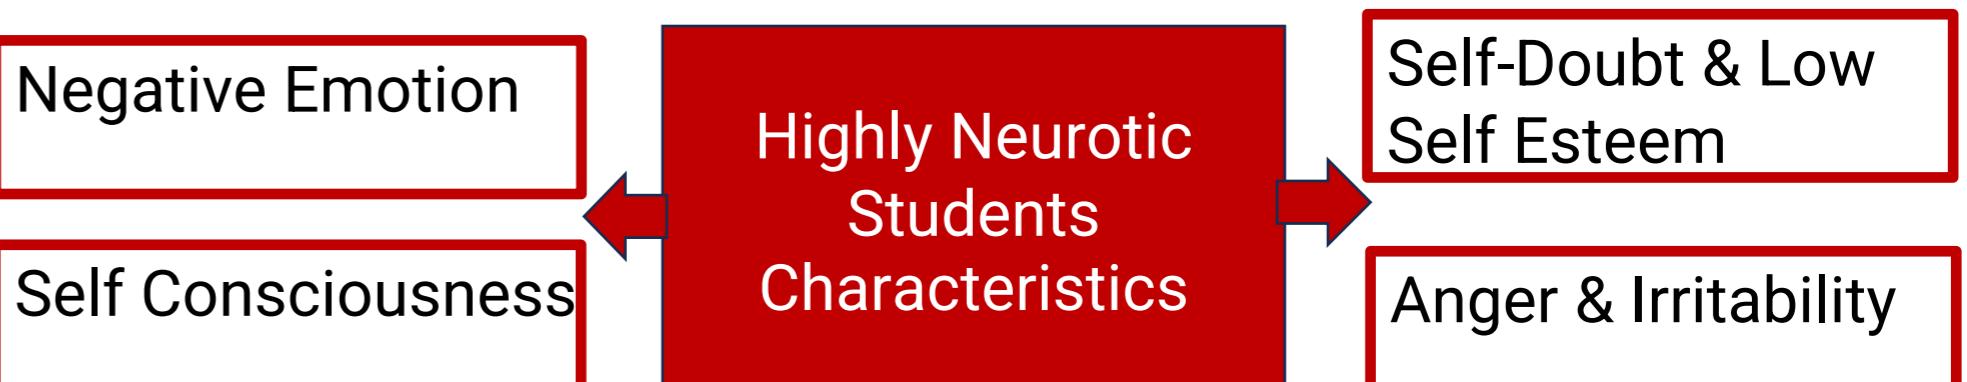

Highly neurotic students with increased depression had more variation in the number of social contacts.

Below table shows more variance, and standard deviation in cluster 1 students' social behavior compared with other two student clusters:

Personality Trait	Variance	Standard Deviation
<b>Cluster 1 Students</b>	<b>0.685</b>	<b>0.828</b>
Cluster 2 Students	0.405	0.636
Cluster 3 Students	0.441	0.664

Our findings indicate that students with neurotic personality traits who experience depression exacerbation show more variation in their number of social contacts POSSIBLY due to low self esteem and negative self-perception.
